(54) Title: METHOD AND APPARATUS FOR DEMODULATING SIGNALS PROCESSED IN A TRANSMIT DIVERSITY MODE

(57) Abstract: Demodulator architectures for processing a received signal in a wireless communications system. The demodulator includes a number of correlators coupled to a combiner. Each correlator typically receives and despreads input samples (which are generated from the received signal) with a respective despreading sequence to provide despread samples. Each correlator then decovers the despread samples to provide recovered "half-symbols" and further demodulates the recovered half-symbols with pilot estimates to generate correlated symbols. The decoding is performed with a Walsh symbol having a length ( $T$ ) that is half the length ( $2T$ ) of a Walsh symbol used to cover the data symbols in the transmitted signal. The combiner selectively combines correlated symbols from the assigned correlators to provide demodulated symbols. One or more correlators can be assigned to process one or more instances of each transmitted signal. The pilot estimates used within each assigned correlator to demodulate the recovered half-symbols are generated based on the signal instance being processed by that correlator.

# METHOD AND APPARATUS FOR DEMODULATING SIGNALS PROCESSED IN A TRANSMIT DIVERSITY MODE

## BACKGROUND OF THE INVENTION

5

### I. Field of the Invention

The present invention relates to data communications. More particularly, the present invention relates to method and apparatus for 10 efficiently demodulating signals that have been processed and transmitted in a diversity mode.

### II. Description of the Related Art

15 In a typical digital communications system, data is processed, modulated, and conditioned at a transmitter unit to generate a modulated signal that is then transmitted to one or more receiver units. The data processing may include, for example, formatting the data into a particular frame format, encoding the formatted data to provide error detection and/or 20 correction at the receiver unit, channelizing (i.e., covering) the coded data, and spreading the channelized data over the system bandwidth. The data processing is typically defined by the system or standard being implemented.

At the receiver unit, the transmitted signal is received, conditioned, demodulated, and digitally processed to recover the transmitted data. The 25 processing at the receiver unit is complementary to that performed at the transmitter unit and may include, for example, despreading the received samples, recovering the despread samples to generate recovered symbols, and decoding the recovered symbols.

In some communications systems, data is processed and redundantly 30 transmitted over two (or possibly more) antennas to provide transmit diversity. The processing may include, for example, covering the data for each antenna with a particular channelization code (e.g., a particular Walsh symbol). In some systems, the data for one or more antennas may also be reordered prior to the channelization. Due to multipath and other phenomena, the transmitted 35 signals may experience different path conditions and may arrive at the receiver unit at different times. If the transmit antennas are spaced sufficiently far apart, then the received signals from the antennas tend to fade independently. Each transmitted signal may also reach the receiver unit via multiple signal paths.

The receiver unit is then required to receive, track, and process one or more instances of each transmitted signal, and to combine the results from the processed signal instances to recover the transmitted data. On the downlink, the processing typically includes tracking a pilot that has been transmitted

5 along with the data, and using the recovered pilot to demodulate data samples.

The signal processing (e.g., demodulation) to process multiple transmitted signals, and multiple instances of such signals, can be complicated. Moreover, transmit diversity is typically provided on the downlink, and user terminals are required to support such a mode. The user terminals are typically

10 more impacted by complexity and costs considerations. Therefore, techniques that can be used to efficiently demodulate signals that have been processed and transmitted in a diversity mode are highly desirable.

## SUMMARY OF THE INVENTION

15

The present invention provides demodulator architectures, demodulators, and receiver units for processing signals that have been processed and transmitted in a transmit diversity mode. When operating in the transmit diversity mode, data symbols are typically covered with a

20 channelization code (e.g., a Walsh symbol) having a length (2T) that is twice the length (T) of the channelization code used to cover the data symbols in the non-transmit diversity mode. The demodulator architectures of the invention exploit this property and perform partial processing (e.g., despreading, decoupling, pilot demodulation, or a combination thereof) on each fraction of a

25 channelization symbol period of 2T. The processed "partial-symbols" are then appropriately combined to generate the demodulated symbols. By performing partial processing on each fraction (e.g., each half) of the symbol period of 2T, computational complexity and costs can be reduced and performance may be improved. For example, with the present invention, the pilot demodulation in

30 each assigned correlator (i.e., finger) can be performed based only on pilot estimates generated by that correlator, whereas conventional techniques may require pilots from multiple correlators. Other advantages are described below.

An embodiment of the invention provides a demodulator for processing a received signal in a wireless communications system. The demodulator

35 includes a number of correlators coupled to a combiner. Each correlator typically receives and despreading input samples with a respective despreading sequence to provide despread samples. The input samples are generated from the received signal. Each correlator then decovers the despread samples to

provide recovered "partial-symbols" and further demodulates the recovered partial-symbols with pilot estimates to generate correlated symbols. The recovering is performed with a channelization symbol (e.g., a Walsh symbol) having a length (e.g., T) that is a fraction (e.g., half) the length 2T of the 5 channelization symbol used to cover the data symbols in the received signal. The combiner receives and selectively combines correlated symbols from the assigned correlators to provide demodulated symbols.

In the transmit diversity mode of a CDMA-2000 or W-CDMA standard (which are identified below), the received signal includes a pair of signals 10 transmitted from a pair of antennas. One or more correlators can then be assigned to process at one or more instances of each transmitted signal. Each assigned correlator processes the received signal to recover pilot estimates corresponding to the signal instance being processed. The pilot estimates are then used within the assigned correlator to demodulate the recovered partial- 15 symbols.

A specific embodiment of the invention provides a demodulator that includes a number of correlators coupled to a combiner. Each correlator typically includes a despreader, a recover element, a complex multiplier, and a switch coupled in series. The despreader receives and despreads input samples 20 with a particular despreading sequence to provide despread samples, and the recover element recovers the despread samples to provide pairs of recovered half-symbols. The recovering is performed with a Walsh symbol  $W$  having a length (T) that is half the length (2T) of a Walsh symbol  $W_{sts}$  used to cover the data in the received signal. (Space-Time Spreading (STS) is a transmit diversity 25 mode defined by the CDMA-2000 standard.) One pair of recovered half-symbols is provided for each Walsh symbol period of 2T. The complex multiplier then demodulates the recovered half-symbols with a pilot recovered by the correlator to provide demodulated half-symbols.

The switch provides a first combination of recovered half-symbols for 30 each Walsh symbol period of 2T in a first (e.g., even) symbol stream and a second combination of recovered half-symbols for each Walsh symbol period of 2T in a second (e.g., odd) symbol stream. The combiner combines the first symbol streams from the correlators to provide a first (even) output symbol stream, and further combines the second symbol streams from the correlators to 35 provide a second (odd) output symbol stream.

In one design of this specific embodiment, the multiplier in each correlator performs a dot product and a cross product between the recovered half-symbols and the pilot to provide "dot" symbols and "cross" symbols,

respectively. The combiner can then be designed to selectively combine the dot and cross symbols for each Walsh symbol period of 2T to provide the demodulated symbols for the first and second output symbol streams.

Another specific embodiment of the invention provides a demodulator

- 5 that also includes a number of correlators coupled to a combiner. Each correlator typically includes a despreader, a decover element, first and second summers, and first and second complex multipliers. The despreader receives and despreads input samples with a particular despreading sequence to provide despread samples, and the decover element decovers the despread
- 10 samples to provide pairs of recovered half-symbols. Again, the recovering is performed with a Walsh symbol  $W$  having a length (T) that is half the length (2T) of a Walsh symbol  $W_{sts}$  used to cover data symbols in the received signal, and one pair of recovered half-symbols is generated for each Walsh symbol period of 2T.
- 15 Each correlator typically further includes a switch coupled to the decover element. The switch provides recovered half-symbols corresponding to the first half of the Walsh symbol period of 2T to a first output and recovered half-symbols corresponding to the second half of the Walsh symbol period of 2T to a second output. Each summer then operatively couples to the outputs of the
- 20 switch and combines each pair of recovered half-symbols in a particular manner to provide a recovered symbol. Each multiplier then demodulates the recovered symbols from a respective summer with a respective pilot to provide a respective symbol stream.

The combiner receives the first and second symbol streams from the first and second multipliers, respectively, of each assigned correlator, combines the first symbol streams from all assigned correlators to provide a first output symbol stream, and further combines the second symbol streams from all assigned correlators to provide a second output symbol stream.

Another embodiment of the invention provides a method for processing

- 30 a received signal in a wireless communications system. The received signal can include a pair of signals transmitted from a pair of antennas. In accordance with the method, input samples are generated from the received signal. At least one signal instance of each transmitted signal is then processed to provide correlated symbols. The processing for each signal instance typically includes
- 35 despreading the input samples with a particular despreading sequence associated with the signal instance being processed to provide despread samples, recovering the despread samples to generate recovered partial-symbols (e.g., half-symbols), and demodulating the recovered partial-symbols

with pilot estimates to generate the correlated symbols for the signal instance. Again, the recovering is performed with a Walsh symbol  $W$  having a length (e.g.,  $T$ ) that is a fraction of (e.g., half) the length ( $2T$ ) of a Walsh symbol  $W_{STS}$  used to cover the data in the received signal. The correlated symbols for all 5 signal instances being processed are then selectively combined to provide demodulated symbols.

The invention further provides other demodulator architectures, correlators, demodulators, receiver units, and methods to process signals that have been processed and transmitted in a transmit diversity mode

10

## BRIEF DESCRIPTION OF THE DRAWINGS

The features, nature, and advantages of the present invention will become more apparent from the detailed description set forth below when 15 taken in conjunction with the drawings in which like reference characters identify correspondingly throughout and wherein:

FIG. 1 is a simplified block diagram of a communications system in which the present invention may be implemented;

FIG. 2 is a block diagram of a modulator that can be used to process a 20 downlink data transmission in a transmit diversity mode in accordance with CDMA-2000 standard;

FIG. 3 is a diagram of a complex multiplier;

FIG. 4 is a block diagram of a conventional demodulator architecture that 25 can be used to demodulate a downlink data transmission that has been processed in the transmit diversity mode; and

FIGS. 5, 6, and 7 are block diagrams of three specific embodiments of a demodulator architecture of the invention, which are also capable of demodulating the downlink data transmission that has been processed in the transmit diversity mode.

30

## DETAILED DESCRIPTION OF THE SPECIFIC EMBODIMENTS

FIG. 1 is a simplified block diagram of an embodiment of a communications system 100 in which the present invention may be 35 implemented. At a transmitter unit 110, traffic data is sent, typically in frames or packets, from a data source 112 to a transmit (TX) data processor 114 that formats, encodes, and processes the data. TX data processor 114 typically further processes signaling and pilot data, which is then combined (e.g., added,

or time division multiplexed) with the processed traffic data to generate composite data. A modulator (MOD) 116 then receives, channelizes (i.e., covers), and spreads the composite data to generate symbols that are then converted to analog signals. The analog signals are filtered, (quadrature) 5 modulated, amplified, and upconverted by a transmitter (TMTR) 118 to generate one or more modulated signals, which are then transmitted via respective antennas 120 to one or more receiver units.

At a receiver unit 130, the transmitted signals are received by an antenna 132 and provided to a receiver (RCVR) 134. Within receiver 134, the received 10 signal is amplified, filtered, downconverted, quadrature demodulated, and digitized to provide inphase (I) and quadrature (Q) samples. A demodulator (DEMOD) 136 then receives, despreads, and decovers the samples to generate recovered symbols. In certain designs, demodulator 136 further demodulates the recovered symbols with pilot estimates to generate demodulated symbols. 15 The demodulated symbols are then decoded and processed by a receive (RX) data processor 138 to recover the transmitted data. The despreading, decoversing, decoding, and processing at receiver unit 130 are performed complementary to the spreading, covering, coding, and processing at transmitter unit 110. The recovered data is then provided to a data sink 140.

20 The signal processing described above supports transmissions of voice, video, packet data, messaging, and other types of communication in one direction. A bi-directional communications system supports two-way data transmission. However, the signal processing for the other direction is not shown in FIG. 1 for simplicity.

25 Communications system 100 can be a code division multiple access (CDMA) system, a time division multiple access (TDMA) communications system (e.g., a GSM system), a frequency division multiple access (FDMA) communications system, or other multiple access communications system that supports voice and data communication between users over a terrestrial link.

30 The use of CDMA techniques in a multiple access communications system is disclosed in U.S. Patent No. 4,901,307, entitled "SPREAD SPECTRUM MULTIPLE ACCESS COMMUNICATION SYSTEM USING SATELLITE OR TERRESTRIAL REPEATERS," and U.S. Patent No. 5,103,459, entitled "SYSTEM AND METHOD FOR GENERATING WAVEFORMS IN A CDMA CELLULAR 35 TELEPHONE SYSTEM". Another specific CDMA system is disclosed in U.S. Patent Application Serial No. 08/963,386, entitled "METHOD AND APPARATUS FOR HIGH RATE PACKET DATA TRANSMISSION," filed

November 3, 1997. These patents and patent application are assigned to the assignee of the present invention and incorporated herein by reference.

CDMA systems are typically designed to conform to one or more standards such as the "TIA/EIA/IS-95-A Mobile Station-Base Station 5 Compatibility Standard for Dual-Mode Wideband Spread Spectrum Cellular System" (hereinafter referred to as the IS-95-A standard), the "TIA/EIA/IS-98 Recommended Minimum Standard for Dual-Mode Wideband Spread Spectrum Cellular Mobile Station" (hereinafter referred to as the IS-98 standard), the standard offered by a consortium named "3rd Generation Partnership Project" 10 (3GPP) and embodied in a set of documents including Document Nos. 3G TS 25.211, 3G TS 25.212, 3G TS 25.213, and 3G TS 25.214 (hereinafter referred to as the W-CDMA standard), and the "TR-45.5 Physical Layer Standard for cdma2000 Spread Spectrum Systems" (hereinafter referred to as the CDMA-2000 standard). New CDMA standards are continually proposed and adopted 15 for use. These CDMA standards are incorporated herein by reference.

FIG. 2 is a block diagram of modulator 116, which can be used to process a downlink data transmission in a Space-Time Spreading transmit diversity mode in accordance with the CDMA-2000 standard (hereinafter referred to as the STS mode). In the STS mode of the CDMA-2000 standard, the data symbols 20  $Y$  to be transmitted are provided to a demultiplexer (DEMUX) 208 and demultiplexed into two complex symbol streams,  $Y_{even}$  and  $Y_{odd}$ , which are then provided to modulators 210a and 210b. The even complex symbol stream  $Y_{even}$  comprises the even inphase symbol stream  $Y_{11}$  and the even quadrature symbol stream  $Y_{Q1}$ . Similarly, the odd complex symbol stream  $Y_{odd}$  comprises the odd 25 inphase symbol stream  $Y_{12}$  and the odd quadrature symbol stream  $Y_{Q2}$ . The even symbol streams comprise "even" indexed data symbols and the odd symbol streams comprise "odd" indexed data symbols. Each modulator 210 performs channelization (i.e., covering) and spreading of the even and odd symbol streams and provides a complex output symbol stream  $S$  for a 30 respective antenna.

In the non-transmit diversity (non-TD) mode of the CDMA-2000 standard, complex data symbols are transmitted serially, with each data symbol having a signaling period of  $T$ . In the STS mode, two complex data symbols are transmitted in parallel over two antennas, with each data symbol having a 35 signaling period of  $2T$ . As defined by the CDMA-2000 standard, within each modulator 210, one of the complex symbol streams (even or odd) is covered with a Walsh symbol  $W_{sts}$  having a length of  $2T$ , and the other complex symbol

stream (odd or even) is covered with a complementary Walsh symbol  $\bar{W}_{sts}$  having a length of  $2T$ .

Within modulator 210a, the even and odd complex symbol streams,  $Y_{even}$  and  $Y_{odd}$ , are provided to symbol repeaters 212a and 212b, respectively. In the

- 5 STS mode, each symbol repeater 212 repeats each received data symbol once to double the signaling period from  $T$  to  $2T$ . The symbol streams from symbol repeaters 212a and 212b are then provided to cover elements 214a and 214b, respectively, which cover the data symbols with a channelization code associated with the physical channel used for the data transmission. In the STS mode, the channelization code for cover element 214a is the Walsh symbol  $W_{sts}$  having a length of  $2T$ , and the channelization code for cover element 214b is the complementary Walsh symbol  $\bar{W}_{sts}$  having the same length of  $2T$ . Each cover element 214 covers (e.g., multiplies) each received data symbol with the Walsh symbol  $W_{sts}$  or  $\bar{W}_{sts}$  in a manner known in the art.
- 10 In the STS mode, the complex symbols from cover element 214b are provided to a complex conjugator 216a that conjugates each received symbol. The conjugated symbols from complex conjugator 216a are then provided to a summer 218a and subtracted from the symbols from cover element 214a to provide complex covered symbols. Each complex covered symbol thus
- 15 includes a pair of data symbols that have been covered with the Walsh symbols  $W_{sts}$  and  $\bar{W}_{sts}$ . The signal processing in the STS mode provides diversity in the transmitted signals, which can result in improved performance.
- 20

In the embodiment shown in FIG. 2, the complex covered symbols from summer 218a are provided to a phase rotator 222a. In an embodiment, phase

- 25 rotator 222a provides a phase rotation of the received complex symbols (e.g., in  $90^\circ$  increments) when enabled by a control signal ROTATE. For example, if the received complex symbols are expressed as  $I_c + jQ_c$ , phase rotator 222a can provide  $90^\circ$  phase rotation of the complex symbols, which can then be expressed as  $-Q_c + jI_c$ . The phase rotation allows modulator 210a to account
- 30 (i.e., compensate) for phase shifts in the modulated signal due to switching or adjustments in the subsequent signal conditioning circuitry within transmitter 118.

A complex multiplier 224a then receives the phase rotated complex symbol stream from phase rotator 222a and a complex spreading sequence  $PN$ ,

- 35 spreads the complex symbol stream with the complex spreading sequence, and provides a complex output symbol stream  $S_t$ . The complex spreading sequence  $PN$  is generated in a manner defined by the particular CDMA system

or standard being implemented. For the CDMA-2000 system, the complex spreading sequence  $PN$  is generated by multiplying the short PN sequences,  $IPN$  and  $QPN$ , assigned to the transmitting base station with the long PN sequence assigned to the receiving user terminal for which the data 5 transmission is destined.

FIG. 3 is a diagram of a complex multiplier 300 that can be used to implement each complex multiplier 224 in FIG. 2. Complex multiplier 300 performs a complex multiply of the complex data symbols,  $D_I + jD_Q$ , with the complex spreading sequence,  $PN_I + jPN_Q$ , to provide complex spread output 10 symbols,  $S_I + jS_Q$ .

Within complex multiplier 300, the inphase data symbols  $D_I$  are provided to multipliers 312a and 312b, and the quadrature data symbols  $D_Q$  are provided to multipliers 312c and 312d. Each of the multipliers 312a and 312d also receives the inphase spreading sequence  $PN_I$ , and each of multipliers 312b 15 and 312c also receives the quadrature spreading sequence  $PN_Q$ . Each multiplier 312 multiplies the received data symbols with the received spreading sequence and provides respective spread symbols. A summer 314a receives and subtracts the output from multiplier 312c from the output from multiplier 312a to provide the inphase output symbols  $S_I$ . A summer 314b receives and 20 combines the outputs from multipliers 312b and 312d to provide the quadrature output symbols  $S_Q$ .

Referring back to FIG. 2, modulator 210b is configured similar to modulator 210a, with three differences. First, in modulator 210b, the complementary Walsh symbol  $\overline{W}_{STS}$  is used to cover the even complex symbol 25 stream  $Y_{even}$ , and the Walsh symbol  $W_{STS}$  is used to cover the odd complex symbol stream  $Y_{odd}$ . Second, complex conjugator 216b couples to the output of cover element 214c (i.e., the processing path for the even complex symbol stream  $Y_{even}$ ). And third, the signs for the inputs of summer 218b are different than the signs for the inputs of summer 216a in modulator 210a.

30 The processing performed by modulator 116 can be described as follows. Initially, the even and odd complex symbol streams can be expressed as:

$$Y_{even} = Y_{I1} + j Y_{Q1} , \text{ and} \quad \text{Eq (1)}$$

$$Y_{odd} = Y_{I2} + j Y_{Q2} . \quad \text{Eq (2)}$$

As defined by the CDMA-2000 standard, the Walsh symbols  $W_{STS}$  and  $\overline{W}_{STS}$  are 35 used to cover the even and odd complex symbol streams. Each of these Walsh

symbols has a length of  $2T$  and can be generated from a Walsh symbol  $W$  of length  $T$  as follows:

$$W_{STS} = WW, \text{ and} \quad \text{Eq (3)}$$

$$\overline{W}_{STS} = W\overline{W},$$

5 where  $\overline{W} = -W$ .

If only the data symbols and the covering are considered (i.e., ignoring the PN spreading, phase rotation, transmit gain, pulse shaping, and other signal processing), the complex output symbol stream for antenna 1 can be expressed as:

$$10 \quad S_1 = Y_{even}WW - Y_{odd}^*W\overline{W}, \quad \text{Eq (4)}$$

where the asterisk (\*) denotes a complex conjugate operation. Similarly, the complex output symbol stream for antenna 2 can be expressed as:

$$S_2 = Y_{even}^*W\overline{W} + Y_{odd}WW. \quad \text{Eq (5)}$$

The complex output symbol streams,  $S_1$  and  $S_2$ , are subsequently provided to two respective processing paths in transmitter 118. Each processing path filters the inphase and quadrature symbol streams,  $S_1$  and  $S_2$ , of the complex symbol stream  $S$ , modulates the filtered  $S_1$  stream with an inphase carrier signal  $\cos(\omega_c t)$ , modulates the filtered  $S_2$  stream with a quadrature carrier signal  $\sin(\omega_c t)$ , sums the two modulated components, and further conditions the resultant signal to generate a modulated signal. In the STS mode, two modulated signals are generated based on two complex symbol streams  $S_1$  and  $S_2$ , and are transmitted from two antennas.

Typically, distinct (i.e., orthogonal) pilots are sent on respective transmit antennas. For example, for the CDMA-2000 system, an unmodulated pilot (using Walsh code 0, 64) is sent on the common antenna and a modulated diversity pilot (using Walsh code 16, 128) is sent on the diversity antenna. The pilots are selected to be orthogonal so that the amplitude and phase of one or both signals transmitted from the respective antennas can be recovered.

The downlink signal processing for the CDMA-2000 standard is described in further detail in the CDMA-2000 standard, and by M. Buehrer et al. in a paper entitled "Proposed Text for Space Time Spreading (STS) v0.3," dated 1999, and incorporated herein by reference. This paper was adopted into the CDMA-2000 standard by the 3GPP2 standard body.

FIG. 4 is a block diagram of a conventional demodulator architecture 400 capable of demodulating a downlink data transmission that has been processed in the STS mode of the CDMA-2000 standard. In the STS mode, the received signal includes two modulated signals that have been transmitted from two 5 transmit antennas. The signal from each transmit antenna typically experiences different path conditions, due to the spatial separation of the transmit antennas, and arrives at the receiver unit distorted by the particular path conditions. At the receiver unit, two or more correlators (i.e., fingers) are used to receive and demodulate the two transmitted signals. The demodulated symbols from the 10 correlators are then combined to recover the transmitted symbols.

Initially, the received signal is conditioned (e.g., amplified, filtered, downconverted, quadrature demodulated, and so on) and digitized to provide a complex sample stream comprised of inphase samples  $I_{IN}$  and quadrature samples  $Q_{IN}$ . The complex sample stream is provided to each correlator 15 assigned to process the received signal. Each correlator receives, tracks, and processes a respective instance (i.e., a particular multipath) of the signal from one of the transmit antennas.

As shown in FIG. 4, a correlator 410a is assigned to receive and process the signal from the first transmit antenna, and a correlator 410b is assigned to 20 receive and process the signal from the second transmit antenna. Within correlator 410a, the complex received samples (i.e.,  $I_{IN} + jQ_{IN}$ ) are provided to a complex multiplier 412a that also receives a complex despreading sequence  $PN_1$  (i.e.,  $PN_1 = PN_{I1} + jPN_{Q1}$ ) having a particular time offset assigned to 25 correlator 410a and matching the time delay of the signal instance being processed. Complex multiplier 412a despreads the complex samples with the  $PN_1$  sequence and provides the complex despread samples (i.e.,  $I_{D1} + jQ_{D1}$ ) to a recover element 414a. Recover element 414a recovers the complex received samples with the Walsh symbol  $W_{STS}$  and provides complex recovered symbols to each of the complex multipliers 420a and 420b. The recovering is achieved 30 by multiplying the inphase (and quadrature) samples with the Walsh symbol  $W_{STS}$  and accumulating the results over the length (2T) of the Walsh symbol  $W_{STS}$  to provide inphase (and quadrature) recovered symbols.

Complex multiplier 420a then demodulates the complex recovered symbols with a conjugated complex pilot  $\hat{h}_1^*$  (estimated from a pilot transmitted 35 from a first transmit antenna) recovered by correlator 410a. Similarly, complex multiplier 420b demodulates the complex recovered symbols with a conjugated complex pilot  $\hat{h}_2^*$  (estimated from a pilot transmitted from a second transmit antenna) recovered by correlator 410b. The output from complex multiplier

420a comprises the even complex symbol stream  $C_{even}^1$  that is provided to an accumulator 442a within a combiner 440. Similarly, the output from complex multiplier 420b comprises the odd complex symbol stream  $C_{odd}^1$  that is provided to an accumulator 442b within combiner 440.

5 Within correlator 410b, the complex received samples (i.e.,  $I_{IN} + jQ_{IN}$ ) are despread by a complex multiplier 412b with a complex despread sequence  $PN_2$  (i.e.,  $PN_2 = PN_{12} + jPN_{Q2}$ ) having a particular time offset assigned to correlator 410b. The complex despread samples (i.e.,  $I_{D2} + jQ_{D2}$ ) are recovered by recover element 414b with the complementary Walsh symbol  $\overline{W}_{STS}$  and 10 conjugated by a complex conjugator 416. The conjugated symbols are then demodulated with the complex pilot  $\hat{h}_2$  by a complex multiplier 420c, and further demodulated with the negative complex pilot  $-\hat{h}_1$  by a complex multiplier 420d. The output from complex multiplier 420c comprises the even complex symbol stream  $C_{even}^2$  that is provided to accumulator 442a, and the 15 output from complex multiplier 420d comprises the odd complex symbol stream  $C_{odd}^2$  that is provided to accumulator 442b.

Accumulator 442a combines the even complex symbol streams,  $C_{even}^1$  and  $C_{even}^2$ , from correlators 410a and 410b and provides the even output symbol stream  $C_{even}$  (i.e.,  $C_{even} = C_{11} + jC_{Q1}$ ). Similarly, accumulator 442b combines the 20 odd complex symbol streams,  $C_{odd}^1$  and  $C_{odd}^2$ , from correlators 410a and 410b and provides the odd output symbol stream  $C_{odd}$  ( $C_{odd} = C_{12} + jC_{Q2}$ ). The symbol streams  $C_{11}$ ,  $C_{Q1}$ ,  $C_{12}$ , and  $C_{Q2}$  are estimates of the symbol streams  $Y_{11}$ ,  $Y_{Q1}$ ,  $Y_{12}$ , and  $Y_{Q2}$ , respectively, generated within modulator 116 in FIG. 2 and expressed in equations (1) and (2).

25 Demodulator architecture 400 is described in further detail by A. Kogiantis et al. in a paper entitled "Downlink Improvement through Space-Time Spreading," dated August 5, 1999, and incorporated herein by reference. This paper was submitted to the 3GPP2 standard body for adoption into the CDMA-2000 standard.

30 Demodulator architecture 400 shown in FIG. 4 has several major disadvantages. First, sharing of information between correlators is required to perform the pilot demodulation. Each correlator 410 performs two complex multiplications to achieve the pilot demodulation. The first complex multiplication is performed between the recovered symbols and the complex 35 pilot estimated by that correlator. The second complex multiplication is performed between the recovered symbols and the complex pilot estimated by the other correlator. Demodulator architecture 400 can be modified to share

decovered symbols instead of pilot estimates. However, in both cases, the need to share information between correlators is highly undesirable in many circuit designs. Additional circuitry would likely be required to coordinate the sharing of information, which would lead to increased complexity and costs.

5 Second, if more than one multipath of any of the transmitted signals is processed, it is necessary to pair up correlators with the same path delay to perform the pilot demodulation. This requirement imposes constraints on the use of the correlators and requires coordination between the correlators.

10 Consequently, as a result of these disadvantages, system performance may be compromised by the use of demodulator architecture 400.

15 FIG. 5 is a block diagram of a specific embodiment of a demodulator architecture 500 of the invention, which is capable of demodulating a downlink data transmission that has been processed in the STS mode of the CDMA-2000 standard. Initially, the received signal is conditioned and digitized to provide a complex sample stream that is provided to each of correlators 510a and 510b. Each correlator 510 receives, tracks, and demodulates a signal transmitted from one of the transmit antennas.

20 Within correlator 510a, the complex received samples (i.e.,  $I_{IN} + jQ_{IN}$ ) are despread by a complex multiplier 512a with a complex despreading sequence  $PN_1$  having a particular time offset assigned to correlator 510a. The complex despread samples (i.e.,  $I_{D1} + jQ_{D1}$ ) are then recovered by recover element 514a with a Walsh symbol  $W$  having a length of  $T$  to provide recovered "half-symbols". The recovering is achieved by multiplying the inphase (and quadrature) samples by the Walsh symbol  $W$  and accumulating the resultant 25 samples over the length ( $T$ ) of the Walsh symbol  $W$ .

30 Referring back to FIG. 2, in the STS mode, each data symbol is covered by the Walsh symbol  $W_{STS}$  or  $\bar{W}_{STS}$  having a length of  $2T$ , which corresponds to one STS symbol period. Also, referring to equation (3), the Walsh symbols  $W_{STS}$  and  $\bar{W}_{STS}$  are generated by combining the Walsh symbol  $W$  and the complementary Walsh symbol  $\bar{W}$ . The Walsh symbols  $W$  and  $\bar{W}$  each has a length of  $T$ , which is half the length of the Walsh symbols  $W_{STS}$  and  $\bar{W}_{STS}$ . Each recovered half-symbol from recover element 514 thus corresponds to only half of the STS symbol period.

35 The complex recovered half-symbols from recover element 514a are provided to a switch 520a. Switch 520a provides the recovered half-symbols corresponding to the first half of the STS symbol period (switch 520a in position A) to a delay element 522a and the recovered half-symbols corresponding to the second half of the STS symbol period (switch 520a in position B) to summers

524a and 524b. Switch 520a can be implemented with a demultiplexer, registers, latches, or some other element. Delay element 522a delays the received half-symbols and provides the delayed half-symbols to summers 524a and 524b. The delay is selected such that the recovered half-symbols for each 5 STS symbol period are aligned in time at the inputs of each of summers 524a and 524b.

For each STS symbol period of 2T (i.e., the length of the Walsh symbols  $W_{STS}$  and  $\bar{W}_{STS}$ ) and after the recovered half-symbol corresponding to the second half of the STS symbol period has been received, summer 524a sums the 10 two received half-symbols and provides the recovered symbol to a complex multiplier 528a. Similarly, for each STS symbol period, summer 524b subtracts the half-symbol received from switch 520a from the half-symbol received from delay element 522a and provides the recovered symbol to a complex conjugator 526a. Complex conjugator 526a conjugates the received symbols and provides 15 the conjugated symbols to a complex multiplier 528b.

Complex multiplier 528a demodulates the complex recovered symbols from summer 524a with a conjugated complex pilot  $\hat{h}_i^*$  recovered by correlator 510a. Similarly, complex multiplier 528b demodulates the complex recovered symbols from complex conjugator 526a with the negated complex pilot  $-\hat{h}_i$ . 20 The output from complex multiplier 528a comprises the even complex symbol stream  $C_{even}^1$  that is provided to an accumulator 542a within a combiner 540, and the output from complex multiplier 528b comprises the odd complex symbol stream  $C_{odd}^1$  that is provided to an accumulator 542b within combiner 540.

Correlator 510b performs similar processing as correlator 510a. Within 25 correlator 510b, the complex received samples (i.e.,  $I_{IN} + jQ_{IN}$ ) are despread by a complex multiplier 512b with a complex despreading sequence  $PN_2$  having a particular time offset assigned to correlator 510b. The complex despread samples are then recovered by recover element 514b with the Walsh symbol  $W$  to provide recovered half-symbols.

30 The complex recovered half-symbols from recover element 514b are provided to a switch 520b, which provides recovered half-symbols corresponding to the first half of the STS symbol period (switch 520b in position A) to a delay element 522b and recovered half-symbols corresponding to the second half of the STS symbol period (switch 520b in position B) to summers 35 524c and 524d. Delay element 522b delays the received half-symbols and provides the delayed half-symbols to summers 524c and 524d. Again, the delay is selected such that the recovered half-symbols for each STS symbol period are

time-aligned at the inputs of each of summers 524c and 524d. For each STS symbol period, summer 524c subtracts the half-symbol received from switch 520b from the half-symbol received from delay element 522b and provides the recovered symbol to a complex conjugator 526b, which conjugates the received symbol and provides the conjugated symbol to a complex multiplier 528c. For each STS symbol period, summer 524d sums the two received half-symbols and provides the recovered symbol to a complex multiplier 528d.

Complex multiplier 528c demodulates the complex recovered symbols from complex conjugator 526b with a complex pilot  $\hat{h}_2$  recovered by correlator 510b. Similarly, complex multiplier 528d demodulates the complex recovered symbols from summer 524d with the conjugated complex pilot  $\hat{h}_2^*$ . The output from complex multiplier 528c comprises the even complex symbol stream  $C_{even}^2$  that is provided to accumulator 542a, and the output from complex multiplier 528d comprises the odd complex symbol stream  $C_{odd}^2$  that is provided to

15 accumulator 542b.

Accumulator 542a combines the even complex symbol streams,  $C_{even}^1$  and  $C_{even}^2$ , from correlators 510a and 510b and provides the even output symbol stream  $C_{even}$  (i.e.,  $C_{even} = C_{I1} + jC_{Q1}$ ). Similarly, accumulator 542b combines the odd complex symbol streams,  $C_{odd}^1$  and  $C_{odd}^2$ , from correlators 510a and 510b and provides the odd output symbol stream  $C_{odd}$  (i.e.,  $C_{odd} = C_{I2} + jC_{Q2}$ ). The symbol streams  $C_{I1}$ ,  $C_{Q1}$ ,  $C_{I2}$ , and  $C_{Q2}$  are estimates of the symbol streams  $Y_{I1}$ ,  $Y_{Q1}$ ,  $Y_{I2}$ , and  $Y_{Q2}$ , respectively, generated within modulator 116 in FIG. 2.

The processing performed by demodulator architecture 500 can be analyzed by first characterizing the transmitted symbol streams. The transmitted symbol streams,  $S_1$  and  $S_2$ , in the STS mode are expressed above in equations (4) and (5). The Walsh symbols  $W_{sts}$  and  $\bar{W}_{sts}$  of length  $2T$  can each be decomposed into a combination of Walsh symbols  $W$  and  $\bar{W}$ , each of length  $T$ . The transmitted symbols can be decomposed into a combination of half-symbols transmitted over the first time interval  $T_1$  of the STS symbol period and half-symbols transmitted over the second time interval  $T_2$  of the STS symbol period.

The transmitted symbols for the first antenna in equation (4) can be expressed as:

$$\begin{aligned}
 S_1 &= S_1^{T1}, S_1^{T2} , \\
 S_1^{T1} &= Y_{even}^* W - Y_{odd}^* W , \text{ and} \\
 S_1^{T2} &= Y_{even}^* W + Y_{odd}^* W .
 \end{aligned} \tag{6}$$

Similarly, the transmitted symbols for the second antenna in equation (5) can be expressed as:

$$\begin{aligned}
 S_2 &= S_2^{T1}, S_2^{T2} , \\
 S_2^{T1} &= Y_{even}^* W + Y_{odd}^* W , \text{ and} \\
 S_2^{T2} &= -Y_{even}^* W + Y_{odd}^* W .
 \end{aligned} \tag{7}$$

5 The signals from the first and second transmit antennas are received with random amplitudes and phases given by the complex values  $h_1$  and  $h_2$ , respectively. The values  $h_1$  and  $h_2$  characterize the path loss and multipath fading experienced by the transmitted signals. If the noise is ignored, the composite received signal can be expressed as:

$$\begin{aligned}
 R &= S_1 h_1, S_2 h_2 = R^{T1}, R^{T2} , \\
 10 \quad R^{T1} &= S_1^{T1} h_1 + S_2^{T1} h_2 , \quad \text{and} \\
 R^{T2} &= S_1^{T2} h_1 + S_2^{T2} h_2 ,
 \end{aligned} \tag{8}$$

where  $R^{T1}$  and  $R^{T2}$  represent the received symbol waveforms for the first and second time intervals,  $T_1$  and  $T_2$ , respectively, of the STS symbol period. The even complex symbol streams  $C_{even}^1$  and  $C_{even}^2$  from correlators 510a and 510b, respectively, can be computed as:

$$\begin{aligned}
 15 \quad C_{even}^1 &= \left( \langle R^{T1}, W \rangle + \langle R^{T2}, W \rangle \right) \hat{h}_1^* \\
 &= \left( \langle (S_1^{T1} h_1 + S_2^{T1} h_2), W \rangle + \langle (S_1^{T2} h_1 + S_2^{T2} h_2), W \rangle \right) \hat{h}_1^* \\
 &= N \left( \left( Y_{even} - Y_{odd}^* \right) + \left( Y_{even}^* + Y_{odd} \right) h_1 + \left( \left( Y_{even}^* + Y_{odd} \right) + \left( -Y_{even}^* + Y_{odd} \right) \right) h_2 \right) \hat{h}_1^* \\
 &= 2N \left( Y_{even} h_1 \hat{h}_1^* + Y_{odd} h_2 \hat{h}_1^* \right) \\
 &= 2N \left( Y_{even} h_1 \hat{h}_1^* + Y_{odd} h_2 \hat{h}_1^* \right) \\
 \end{aligned} \tag{9}$$

$$\begin{aligned}
C_{even}^2 &= \langle R^{T1}, W \rangle - \langle R^{T2}, W \rangle \hat{h}_2 \\
&= \langle (S_1^{T1} h_1 + S_2^{T1} h_2), W \rangle - \langle (S_1^{T2} h_1 + S_2^{T2} h_2), W \rangle \hat{h}_2 \\
&= N \langle (Y_{even} - Y_{odd}^*) - (Y_{even} + Y_{odd}^*) \rangle h_1^* + \langle (Y_{even}^* + Y_{odd}) - (-Y_{even}^* + Y_{odd}) \rangle h_2^* \hat{h}_2 \\
&= 2N \langle -Y_{odd} h_1^* \hat{h}_2 + Y_{even} h_2^* \hat{h}_2 \rangle
\end{aligned}$$

Eq (10)

where  $\langle R^{T1}, W \rangle$  denotes the recovering of the symbol waveform  $R^{T1}$  by the first correlator with the Walsh symbol  $W$ ,  $2N$  represents the length of the Walsh symbols  $W_{STS}$  and  $\bar{W}_{STS}$  (in chips), and  $(AB)^* = A^* B^*$ . Similarly, the odd complex symbol streams  $C_{odd}^1$  and  $C_{odd}^2$  from correlators 510a and 510b, respectively, can be computed as:

$$\begin{aligned}
C_{odd}^1 &= -\langle R^{T1}, W \rangle - \langle R^{T2}, W \rangle \hat{h}_1 \\
&= -\langle (S_1^{T1} h_1 + S_2^{T1} h_2), W \rangle - \langle (S_1^{T2} h_1 + S_2^{T2} h_2), W \rangle \hat{h}_1 \\
&= -N \langle (Y_{even} - Y_{odd}^*) - (Y_{even} + Y_{odd}^*) \rangle h_1^* + \langle (Y_{even}^* + Y_{odd}) - (-Y_{even}^* + Y_{odd}) \rangle h_2^* \hat{h}_1 \\
&= 2N \langle Y_{odd} h_1^* \hat{h}_1 - Y_{even} h_2^* \hat{h}_1 \rangle
\end{aligned}$$

Eq (11)

10

$$\begin{aligned}
C_{odd}^2 &= \langle R^{T1}, W \rangle + \langle R^{T2}, W \rangle \hat{h}_2^* \\
&= \langle (S_1^{T1} h_1 + S_2^{T1} h_2), W \rangle + \langle (S_1^{T2} h_1 + S_2^{T2} h_2), W \rangle \hat{h}_2^* \\
&= N \langle (Y_{even} - Y_{odd}^*) + (Y_{even} + Y_{odd}^*) \rangle h_1 + \langle (Y_{even}^* + Y_{odd}) + (-Y_{even}^* + Y_{odd}) \rangle h_2 \hat{h}_2^* \\
&= 2N \langle Y_{even} h_1 \hat{h}_2^* + Y_{odd} h_2 \hat{h}_2^* \rangle
\end{aligned}$$

Eq (12)

The even complex symbol stream  $C_{even}$  from combiner 542a and the odd complex symbol stream  $C_{odd}$  from combiner 542b can be expressed as:

$$\begin{aligned}
C_{even} &= C_{even}^1 + C_{even}^2 , \\
&= 2N \langle Y_{even} h_1 \hat{h}_1^* + Y_{odd} h_2 \hat{h}_1^* \rangle + 2N \langle -Y_{odd} h_1^* \hat{h}_2 + Y_{even} h_2^* \hat{h}_2 \rangle , \text{ Eq (13)} \\
&= 2N \langle Y_{even} (h_1 \hat{h}_1^* + h_2 \hat{h}_2^*) + Y_{odd} (h_2 \hat{h}_1^* - h_1 \hat{h}_2^*) \rangle ,
\end{aligned}$$

15

$$\begin{aligned}
C_{odd} &= C_{odd}^1 + C_{odd}^2 , \\
&= 2N \langle Y_{odd} h_1^* \hat{h}_1 - Y_{even} h_2^* \hat{h}_1 \rangle + 2N \langle Y_{even} h_1 \hat{h}_2^* + Y_{odd} h_2 \hat{h}_2^* \rangle , \text{ Eq (14)} \\
&= 2N \langle Y_{odd} (h_1 \hat{h}_1^* + h_2 \hat{h}_2^*) + Y_{even} (h_1 \hat{h}_2^* - h_2 \hat{h}_1) \rangle .
\end{aligned}$$

In each of equations (13) and (14), the first term is the desired signal component and the second term is the undesired component due to cross-talk. If the pilot estimates are accurate (i.e.,  $\hat{h}_1 = h_1$  and  $\hat{h}_2 = h_2$ ), then equations (13) and (14) simplify as follows:

$$5 \quad C_{even} = 2N Y_{even} \left( |h_1|^2 + |h_2|^2 \right) , \quad \text{Eq (15)}$$

$$C_{odd} = 2N Y_{odd} \left( |h_1|^2 + |h_2|^2 \right) . \quad \text{Eq (16)}$$

Demodulator architecture 500 can recover the transmitted symbols if one transmit antenna should fail to operate or if the signal transmitted from one of the antennas experiences a deep fade. As an example, if the second transmit antenna should fail, the received symbol stream can be expressed as:

$$\begin{aligned} R &= S_1 h_1 , \\ R^{T1} &= S_1^{T1} h_1 , \text{ and} \\ R^{T2} &= S_1^{T2} h_1 . \end{aligned} \quad \text{Eq (17)}$$

At the receiver unit, one correlator can be used to receive and process the transmitted signal. The even and odd complex symbol streams,  $C_{even}$  and  $C_{odd}$ , from the assigned correlator can be expressed as:

$$\begin{aligned} 15 \quad C_{even}^1 &= \left( \langle R^{T1}, W \rangle + \langle R^{T2}, W \rangle \right) \hat{h}_1^* , \\ &= \left( \langle S_1^{T1} h_1, W \rangle + \langle S_1^{T2} h_1, W \rangle \right) \hat{h}_1^* , \\ &= N \left( \left( \langle Y_{even} - Y_{odd}^* \rangle + \langle Y_{even} + Y_{odd}^* \rangle \right) h_1 \right) \hat{h}_1^* , \\ &= 2N \left( Y_{even} h_1 \hat{h}_1^* \right) . \end{aligned} \quad \text{Eq (18)}$$

$$\begin{aligned} C_{odd}^1 &= - \left( \langle R^{T1}, W \rangle - \langle R^{T2}, W \rangle \right)^* \hat{h}_1 \\ &= - \left( \langle S_1^{T1} h_1, W \rangle - \langle S_1^{T2} h_1, W \rangle \right)^* \hat{h}_1 \\ &= - N \left( \left( \langle Y_{even} - Y_{odd}^* \rangle - \langle Y_{even} + Y_{odd}^* \rangle \right)^* h_1 \right) \hat{h}_1 \\ &= 2N \left( Y_{odd} h_1^* \hat{h}_1 \right) \end{aligned} \quad \text{Eq (19)}$$

Again, if the pilot estimate is accurate (i.e.,  $\hat{h}_1 = h_1$ ), then equations (18) and (19) simplify as follows:

$$C_{even}^1 = 2N Y_{even} \left( |h_1|^2 \right) ,$$

$$C_{odd}^1 = 2N Y_{odd} \left( |h_1|^2 \right) .$$

Demodulator architecture 500 shown in FIG. 5 provides a number of advantages over demodulator architecture 400 shown in FIG. 4. These 5 advantages can result in a simplified design, reduced costs, improved performance, some other advantages, or a combination thereof. Some of these advantages are described below.

First, demodulator architecture 500 does not require the sharing of pilot estimates and data symbols between correlators. Each correlator receives, 10 processes, and demodulates the received sample stream with its own pilot estimate. The autonomous design for the correlators eliminates the need to transfer information between correlators and simplifies the design of the receiver unit that uses demodulator architecture 500.

Second, demodulator architecture 500 does not require correlators to be 15 paired up. This allows for flexibility in assigning correlators to the strongest signal instances, which can lead to improved performance.

Third, demodulator architecture 500 does not require synchronization of the pilots of paired correlators that have unequal path delays. This feature results from the ability of each correlator to operate independently based on the 20 received samples and its own pilot estimate. In contrast, since the correlators are operated in pairs in demodulator architecture 400, the pilots needs to be properly aligned in time to account for any delays between the signal instances being processed by the pair of correlators.

Fourth, demodulator architecture 500 allows for reception of the 25 transmitted symbols if one of the transmit antennas should fail to operate or is in a deep fade. In contrast, demodulator architecture 400 can only recover half of the transmitted symbol should one transmit antenna fail. Demodulator architecture 500 can be used to provide a more robust and reliable communication.

30 FIG. 6 is a block diagram of another specific embodiment of a demodulator architecture 600 of the invention, which is also capable of demodulating a downlink data transmission that has been processed in the STS mode of the CDMA-2000 standard. The complex sample stream is provided to correlators 610a and 610b, with each correlator 610 operated to receive, track, and demodulate a signal transmitted from one of the transmit antennas.

Within correlator 610a, the complex received samples are despread by a complex multiplier 612a with a despread sequence  $PN_1$  and recovered by a recover element 614a with the Walsh symbol  $W$  to provide recovered half-symbols. The recovered half-symbols are then demodulated with a conjugated complex pilot  $\hat{h}_1$  recovered by correlator 610a to provide demodulated half-symbols, which are then provided to a switch 620a. In the first half of the STS symbol period, switch 620a is in position A, and the demodulated half-symbol is provided to a signal path 622a and the inverted demodulated half-symbol is provided to a signal path 622b. In the second half of the STS symbol period, switch 620a is in position B, and the demodulated half-symbol is provided to signal paths 622a and 622b. Switch 620a can be implemented with a demultiplexer or some other element.

The demodulated half-symbols on signal path 622a are provided to an accumulator 642a within a combiner 640. The demodulated half-symbols on signal path 622b are provided to a complex conjugator 626a, which conjugates the received half-symbols and provides the conjugated half-symbols to an accumulator 642b within combiner 640.

Correlator 610b processes the complex received samples in similar manner as correlator 610a. Specifically, correlator 610b despreads the complex received samples with a despread sequence  $PN_2$ , decovers the despread samples with the Walsh symbol  $W$  to provide recovered half-symbols, and demodulates the recovered half-symbols with a conjugated complex pilot  $\hat{h}_2$  recovered by correlator 610b to provide demodulated half-symbols. The demodulated half-symbols corresponding to the first half of the STS symbol period are provided to accumulator 642b, and also conjugated and provided to accumulator 642a. Similarly, the demodulated half-symbols corresponding to the second half of the STS symbol period are provided to accumulator 642b, and also inverted and conjugated and provided to accumulator 642a.

For each STS symbol period, accumulator 642a combines the four received demodulated half-symbols and provides an even output symbol, and accumulator 642b combines the four received demodulated half-symbols to provide an odd output symbol.

Demodulator architecture 600 generates equivalent results as demodulator architecture 500 in FIG. 5. However, by performing the pilot demodulation after the recovering, only one complex multiplier is required. Complex multiplier 616 performs one complex multiply (e.g., one dot product and one cross product) for each half of the STS symbol period (i.e., each period

of T). In contrast, each of multipliers 528 in demodulator architecture 500 performs one complex multiply for each STS symbol period of 2T.

Also, the summers (i.e., summers 524) used to combine the recovered half-symbols for each STS symbol period are not needed in demodulator 5 architecture 600 since this function is performed by accumulators 642a and 642b. Each accumulator 642 performs twice the number of read-accumulate-write operations for each STS symbol period as accumulator 542 in demodulator architecture 500.

FIG. 7 is a block diagram of yet another specific embodiment of a demodulator architecture 700 of the invention, which is also capable of demodulating a downlink data transmission that has been processed in the STS mode of the CDMA-2000 standard. The complex sample stream is provided to correlators 710a and 710b, with each correlator 710 operated to receive, track, and demodulate a signal transmitted from one of the transmit antennas.

Within each correlator 710, the complex received samples are despread by a complex multiplier 712 with a despreading sequence  $PN$  having a particular time offset assigned to that correlator, recovered by a recover element 714 with the Walsh symbol  $W$  to provide recovered half-symbols, and demodulated by a complex multiplier 716 with a conjugated complex pilot  $\hat{h}^*$  recovered by that correlator to provide demodulated half-symbols.

Within correlator 710a, a switch 720a provides demodulated half-symbols corresponding to the first half of the STS symbol period to an accumulator 742a within a combiner 740 and further provides demodulated half-symbols corresponding to the second half of the STS symbol period to an accumulator 742b within combiner 740. Similarly, within correlator 710b, a switch 720b provides demodulated half-symbols corresponding to the first half of the STS symbol period to an accumulator 742c and demodulated half-symbols corresponding to the second half of the STS symbol period to an accumulator 742d. Each accumulator 742 selectively combines the received half-symbols to provide the output symbols.

In FIG. 7, complex multipliers 716a and 716b are each configured to perform two complex multiplies for each STS symbol period. The complex multiply from correlator  $n$  for time interval  $Tx$  of the STS symbol period can be expressed as:

$$\begin{aligned}
 C^n &= (X_I + jX_Q)(P_I - jP_Q) , \\
 &= (X_I P_I + X_Q P_Q) + j(X_Q P_I - X_I P_Q) , \\
 &= C_{dot}^{n,Tx} + j C_{cross}^{n,Tx} ,
 \end{aligned} \tag{20}$$

where  $X_I + jX_Q$  is the complex recovered half-symbol to be demodulated,  $P_I - jP_Q$  is the conjugated pilot estimate (e.g.,  $\hat{h}^* = P_I - jP_Q$ ), and  $C_{dot}^{n,Tx}$  and  $C_{cross}^{n,Tx}$  are the dot and cross products, respectively, for the complex multiply.

5 As shown in equation (20), each complex multiply can be performed with a dot product and a cross product. The four complex multiplies performed by multipliers 716a and 716b for each STS symbol period can be achieved with four dot products and four cross products, which yield four "dot" symbols and four "cross" symbols, respectively. The dot and cross symbols are  
10 also referred to as intermediate symbols. In an embodiment, the eight intermediate symbols for each STS symbol period can be stored to eight memory locations and later combined when the symbols are retrieved from memory.

15 The symbol combination performed by accumulators 742 can be computed as follows. In correlator 710a, the dot and cross products generate the intermediate symbols  $C_{dot}^{1,T1}$  and  $C_{cross}^{1,T1}$ , respectively, in the first half of the STS symbol period and the intermediate symbols  $C_{dot}^{1,T2}$  and  $C_{cross}^{1,T2}$ , respectively, in the second half of the STS symbol period. Similarly, in correlator 710b, the dot and cross products generate the intermediate symbols  $C_{dot}^{2,T1}$  and  $C_{cross}^{2,T1}$ , respectively, in the first half of the STS symbol period and the intermediate symbols  $C_{dot}^{2,T2}$  and  $C_{cross}^{2,T2}$ , respectively, in the second half of the STS symbol period. The even complex output symbols  $C_{even}$  can be expressed as:

$$\begin{aligned}
 C_{even} &= C_{even}^I + jC_{even}^Q , \\
 C_{even}^I &= C_{dot}^{1,T1} + C_{dot}^{1,T2} + C_{dot}^{2,T1} - C_{dot}^{2,T2} , \text{ and} \\
 C_{even}^Q &= C_{cross}^{1,T1} + C_{cross}^{1,T2} - C_{cross}^{2,T1} + C_{cross}^{2,T2} .
 \end{aligned} \tag{21}$$

Similarly, the odd complex output symbols  $C_{odd}$  can be expressed as:

$$\begin{aligned}
 C_{odd} &= C_{odd}^I + jC_{odd}^Q , \\
 C_{odd}^I &= -C_{dot}^{1,T1} + C_{dot}^{1,T2} + C_{dot}^{2,T1} + C_{dot}^{2,T2} , \text{ and} \\
 C_{odd}^Q &= C_{cross}^{1,T1} - C_{cross}^{1,T2} + C_{cross}^{2,T1} + C_{cross}^{2,T2} .
 \end{aligned} \tag{22}$$

To further simplify the computations, equations (21) and (22) may be expressed as:

$$\begin{aligned}
 C_{even}^I &= (C_{dot}^{1,T1} + C_{dot}^{1,T2} + C_{dot}^{2,T1} + C_{dot}^{2,T2}) - 2C_{dot}^{2,T2} , \\
 C_{even}^Q &= (C_{cross}^{1,T1} + C_{cross}^{1,T2} + C_{cross}^{2,T1} + C_{cross}^{2,T2}) - 2C_{cross}^{2,T1} , \\
 C_{odd}^I &= (C_{dot}^{1,T1} + C_{dot}^{1,T2} + C_{dot}^{2,T1} + C_{dot}^{2,T2}) - 2C_{dot}^{1,T1} , \\
 C_{odd}^Q &= (C_{cross}^{1,T1} + C_{cross}^{1,T2} + C_{cross}^{2,T1} + C_{cross}^{2,T2}) - 2C_{cross}^{1,T2} .
 \end{aligned} \tag{Eq 23}$$

In equation (23), the quantity within the parenthesis can be computed 5 once for the dot products and once for the cross products for each STS symbol period. Two such combined symbols can be computed for each STS symbol period. For each output symbol (e.g.,  $C_{even}^I$ ), a corresponding intermediate symbol (e.g.,  $C_{dot}^{2,T2}$ ) is scaled by a factor of two (e.g., shifted left by one bit) and subtracted from a corresponding combined symbol (e.g.,  $10 C_{dot}^{1,T1} + C_{dot}^{1,T2} + C_{dot}^{2,T1} + C_{dot}^{2,T2}$ ).

FIGS. 5, 6, and 7 show three specific embodiments of the present invention. Other embodiments can also be designed and are within the scope of the present invention. Generally, the demodulator architectures of the present invention perform partial processing (e.g., despreading, decovering, 15 pilot demodulation, or a combination thereof) on fractions (e.g., half, quarter, and so on) of the STS symbol period to generate processed "partial-symbols". The processed partial-symbols are then appropriately further processed and combined to generate the output symbols. By performing partial processing on each fraction of the STS symbol period, numerous benefits described above are 20 achieved.

The present invention has been described with designs in which the partial processing is performed on half-symbols. However, partial processing on other fractions of the symbol period may also be performed and are within the scope of the present invention. For example, the partial processing may be 25 performed on quarter symbol period, eighth symbol period, or some other fraction.

In the embodiments shown in FIGS. 5, 6, and 7, two correlators are used to process the two signals transmitted from two antennas. Each of these correlators can be operated to track the timing corresponding to the signal 30 instances being processed.

The signals from the two transmit antennas may also be processed based on the same timing (e.g., the timing of one of the signal instances being

processed, or the average timing of the two signal instances, or others). In this implementation, the same symbols are used for both transmitted signals, and the processing can be performed by a single (modified) correlator. The modified correlator can be designed to perform despreading and recovering 5 with a particular time offset, and two pilot demodulation. Common sampling, decimation, despreading, and recovering are performed for both transmitted signals. The use of the same timing may result in higher cancellation of cross-talk, which can provide improved performance.

The demodulator architectures of the invention can be employed in 10 various receiver architectures such as, for example, a rake receiver. The design and operation of a rake receiver for an CDMA system is described in further detail in U.S. Patent No. 5,764,687, entitled "MOBILE DEMODULATOR ARCHITECTURE FOR A SPREAD SPECTRUM MULTIPLE ACCESS COMMUNICATION SYSTEM," and U.S. Patent No. 5,490,165, entitled 15 "DEMODULATION ELEMENT ASSIGNMENT IN A SYSTEM CAPABLE OF RECEIVING MULTIPLE SIGNALS," both assigned to the assignee of the present invention and incorporated herein by reference.

The rake receiver typically includes many correlators (i.e., fingers) that are assigned to process strong instances of the received signal. The 20 demodulator architectures of the invention allow for easy combining of symbols or half-symbols from multiple assigned correlators. For example, referring back to FIG. 4, the even complex symbols from each assigned correlator are provided to accumulator 442a and the odd complex symbols from each assigned correlator are provided to accumulator 442b. For each STS 25 symbol period, each accumulator 442 combines all received symbols and provides a complex output symbol. Generally, the rake receiver using the demodulator architectures of the invention can be designed to include as many correlators as desired. Each accumulator is then designed to accumulate symbols from all assigned correlators.

30 The processing to recover the transmitted pilot is known in the art and not described in detail herein. The pilot processing is dependent in the particular CDMA system or standard being implemented. For example, different pilot processing is typically performed depending on whether the pilot is added to (i.e., superimposed over) the data or time division multiplexed 35 with the data. An example of the pilot processing is described in the aforementioned U.S. Patent Application Serial No. 5,764,687 and 5,490,165.

For clarity, the demodulator architectures, demodulators, and receiver units of the invention have been described specifically for the STS mode defined

by the CDMA-2000 standard. The invention can also be used in other communications systems that employ the same, similar, or different transmit diversity modes. The demodulator architecture of the invention can be used to provide the basic functionality (e.g., decovering, pilot demodulation, and so on). Modification of the basic functionality and/or additional processing (e.g., combining, reordering of the symbols, and so on) may be implemented to achieve the desired results.

For example, the W-CDMA standard provides a space time block coding transmit antenna diversity (STTD) mode in which symbols are transmitted 10 redundantly over two antennas. In the STTD mode, data symbols are redundantly sent to two modulators, but the symbols provided to the second modulator are reordered, with respect to the symbols provided to the first modulator, in accordance with a particular ordering scheme. To support the STTD mode, demodulator architectures of the invention can be modified to 15 temporarily store the demodulated symbols from the assigned correlators, reorder the symbols in the inverse manner, and combine the symbols to recover the transmitted symbols.

The demodulator architectures described above can be advantageously used in a user terminal (e.g., a mobile unit, a telephone, and so on) of a 20 communications system, and may also be used at a base station. The signal processing for the downlink and uplink may be different and is typically dependent on the particular CDMA standard or system being implemented. Thus, the demodulator architectures are typically adopted especially for the particular application for which it is used.

25 Some or all of the elements described above for the demodulator architectures of the invention (e.g., the complex multipliers, decover elements, switches, delay elements, summers, combiner, and so on) can be implemented within one or more application specific integrated circuits (ASICs), digital signal processors (DSPs), controllers, micro-controllers, microprocessors, 30 programmable logic devices (PLDs), other electronic units designed to perform the functions described herein, or a combination thereof. Also, some or all of the elements described above can be implemented using software or firmware executed on a processor.

As an example, a demodulator can be designed in which the despreader 35 and decover elements for each correlator are implemented in hardware, and the pilot demodulation and symbol accumulation for all correlators are performed by a DSP in a time division multiplexed manner. As another example, one correlator and combiner can be implemented and used to process

samples corresponding to various signal instances in a time division multiplexed manner. Numerous other implementations can be contemplated and are within the scope of the present invention.

The foregoing description of the preferred embodiments is provided to enable any person skilled in the art to make or use the present invention. Various modifications to these embodiments will be readily apparent to those skilled in the art, and the generic principles defined herein may be applied to other embodiments without the use of the inventive faculty. Thus, the present invention is not intended to be limited to the embodiments shown herein but is 10 to be accorded the widest scope consistent with the principles and novel features disclosed herein.

**WHAT IS CLAIMED IS:**

## CLAIMS

2

1. A demodulator for processing a received signal in a wireless  
2 communications system, comprising:

4 a plurality of correlators, each correlator operative to receive and  
6 recover a plurality of input samples generated from the received signal to  
8 provide recovered half-symbols, and to demodulate the recovered half-  
10 symbols with pilot estimates to generate correlated symbols, wherein the  
12 recovering is performed with a channelization symbol having a length (T) that  
is half the length (2T) of a channelization symbol used to cover data symbols in  
the received signal; and  
10 a combiner coupled to the plurality of correlators, the combiner  
operative to receive correlated symbols from each of the plurality of correlators  
12 and to selectively combine the correlated symbols to provide demodulated  
symbols.

2. The demodulator of claim 1, wherein each correlator is further  
4 operative to receive and despread the plurality of input samples with a  
6 respective despreading sequence to provide a plurality of despread samples,  
and

6 wherein the recovering is performed by the correlators on the plurality  
6 of despread samples.

2. The demodulator of claim 2, wherein the despreading and recovering  
2 are performed based on a common timing.

4. The demodulator of claim 1, wherein one of the correlators is  
2 operative to receive and recover the plurality of input samples generated from  
the received signal to provide the recovered half-symbols, and wherein each  
4 correlator is operative to receive and demodulate the recovered half-symbols  
with a pilot estimate from the correlator to generate correlated symbols

5. The demodulator of claim 1, wherein the received signal includes data  
2 symbols that have been covered with a Walsh symbol  $W_{sts}$  having a length of  
2T and data symbols that have been covered with a complementary Walsh  
4 symbol  $\bar{W}_{sts}$  also having a length of 2T.

6. The demodulator of claim 1, wherein the received signal includes a  
2 first signal transmitted from a first antenna and a second signal transmitted  
4 from a second antenna, and wherein the demodulator comprises one or more  
6 correlators assigned to process one or more instances of the first signal and one  
or more correlators assigned to process one or more instances of the second  
signal.

7. The demodulator of claim 1, wherein the pilot estimates used within  
2 each correlator to demodulate the recovered half-symbols are generated based  
on a signal instance being processed by that correlator.

8. The demodulator of claim 1, wherein the received signal conforms to  
2 CDMA-2000 standard or W-CDMA standard.

9. A demodulator for processing a received signal in a communications  
2 system, the demodulator comprising:

4 a plurality of correlators, each correlator operative to receive and  
provide first and second symbol streams, wherein each correlator includes

6 a deciver element operative to receive and deciver the plurality  
8 of input samples to provide pairs of decivered half-symbols, wherein the  
10 decoving is performed with a Walsh symbol  $W$  having a length (T)  
12 that is half the length (2T) of a Walsh symbol  $W_{S3S}$  used to cover data  
14 symbols in the received signal, and wherein one pair of decivered half-  
16 symbols is provided for each Walsh symbol period of 2T,

18 first and second summers operatively coupled to the deciver  
element, each summer operative to combine each pair of decivered half-  
20 symbols in a particular manner to provide a respective decivered  
symbol, and

22 first and second multipliers respectively coupled to the first and  
second summers, each multiplier operative to receive and demodulate  
decivered symbols from the respective summer with a respective pilot to  
provide the first or second symbol stream; and

24 a combiner coupled to the plurality of correlators, the combiner  
operative to receive the first and second symbol streams from the first and  
26 second multipliers, respectively, of each of the plurality of correlators, combine  
the first symbol streams from the plurality of correlators to provide a first

24 output symbol stream, and combine the second symbol streams from the plurality of correlators to provide a second output symbol stream.

10. The demodulator of claim 9, wherein each correlator further includes  
2 a despreader operative to receive and despread the plurality of input samples with a particular despreading sequence to provide a plurality of 4 despread samples, and

6 wherein the decov element is coupled to the despreader and operative to receive and recover the plurality of despread samples.

11. The demodulator of claim 9, wherein each correlator further includes  
2 a switch coupled to the decov element and operative to

receive the pairs of recovered half-symbols,

4 provide recovered half-symbols corresponding to a first half of the Walsh symbol period of 2T to a first output, and

6 provide recovered half-symbols corresponding to a second half of the Walsh symbol period of 2T to a second output, and

8 wherein the first and second summers are operatively coupled to the first and second outputs, respectively, of the switch.

12. The demodulator of claim 11, wherein each correlator further includes  
2

4 a delay element coupled to the first output of the switch and the first summer.

13. A demodulator for processing a received signal in a communications system, the demodulator comprising:

2 a plurality of correlators, each correlator operative to receive and 4 demodulate a plurality of input samples generated from the received signal to provide first and second symbol streams, wherein each correlator includes

6 a decov element operative to receive and recover the plurality of input samples to provide pairs of recovered half-symbols, wherein the 8 recovering is performed with a Walsh symbol  $W$  having a length (T) that is half the length (2T) of a Walsh symbol  $W_{sts}$  used to cover data

10 symbols in the received signal, and wherein one pair of recovered half-symbols is provided for each Walsh symbol period of 2T,

12            a multiplier coupled the decover element and operative to receive  
13            and demodulate the recovered half-symbols with a pilot recovered by  
14            the correlator to provide demodulated half-symbols, and  
15            a switch coupled to the multiplier and operative to provide a first  
16            combination of recovered half-symbols for each Walsh symbol period of  
17            2T in a first symbol stream and to provide a second combination of  
18            recovered half-symbols for each Walsh symbol period of 2T in a second  
19            symbol stream; and  
20            a combiner coupled to the plurality of correlators, the combiner  
21            operative to receive the first and second symbol streams from each of the  
22            plurality of correlators, combine the first symbol streams from the plurality of  
23            correlators to provide a first output symbol stream, and combine the second  
24            symbol streams from the plurality of correlators to provide a second output  
symbol stream.

14. The demodulator of claim 13, wherein each correlator further  
2 includes

4            a despread operative to receive and despread the plurality of input  
samples with a particular despreading sequence to provide a plurality of  
5            despread samples, and  
6            wherein the decover element is coupled to the despread and operative  
to receive and recover the plurality of despread samples.

15. The demodulator of claim 13, wherein the multiplier in each  
2 correlator is operative to perform a dot product between the recovered half-  
symbols and the pilot to provide dot symbols, and to perform a cross product  
4 between the recovered half-symbols and the pilot to provide cross symbols,  
and

6            wherein the combiner is operative to selectively combine dot symbols  
and cross symbols for each Walsh symbol period of 2T to provide demodulated  
8            symbols for the first and second output symbol streams.

16. A correlator for processing a received signal in a communications  
2 system, comprising:

4            a decover element operative to receive and recover a plurality of input  
samples generated from the received signal to provide pairs of recovered half-  
symbols, wherein the recovering is performed with a channelization symbol  
6            having a length (T) that is half the length (2T) of a channelization symbol used

to cover data symbols in the received signal, and wherein one pair of recovered half-symbols is provided for each channelization symbol period of 2T; and

8 one or more multipliers operatively coupled to the recover element, each

10 multiplier operative to receive and demodulate recovered half-symbols with a respective pilot to provide correlated symbols.

17. The correlator of claim 16, further comprising:

2 a despreader operative to receive and despread the plurality of input samples with a despreading sequence to provide a plurality of despread

4 samples, and

6 wherein the recover element is coupled to the despreader and operative to receive and recover the plurality of despread samples.

18. A correlator for processing a received signal in a communications system, comprising:

2 a despreader operative to receive and despread the plurality of input samples with a despreading sequence to provide a plurality of despread samples;

6 a recover element coupled to the despreader and operative to receive and recover a plurality of despread samples to provide pairs of recovered half-symbols, wherein the recovering is performed with a Walsh symbol  $W$  having a length (T) that is half the length (2T) of the Walsh symbols  $W_{sts}$  and  $\bar{W}_{sts}$  used

8 to cover data symbols in the received signal, and wherein one pair of recovered half-symbols is provided for each Walsh symbol period of 2T; and

10 a multiplier operatively coupled to the recover element and operative to receive and demodulate recovered half-symbols with a pilot to provide

12 correlated symbols.

19. A receiver unit in a wireless communications system, comprising:

2 a receiver operative to process a received signal to provide a plurality of samples; and

4 a demodulator coupled to the receiver and operative to receive and demodulate the plurality of samples to provide demodulated symbols, the

6 demodulator including

8 a plurality of correlators, each correlator operative to receive and recover the plurality of samples to provide recovered symbols or half-symbols and to demodulate the recovered symbols or half-symbols with

10 a respective pilot to generate correlated symbols, wherein the recovering

12 is performed with a Walsh symbol  $W$  having a length (T) that is half the  
length (2T) of a Walsh symbol  $W_{STS}$  used to cover data symbols in the  
received signal, and

14 a combiner coupled to the plurality of correlators and operative to  
receive correlated symbols from each of the plurality of correlators and  
16 to selectively combine the correlated symbols to provide the  
demodulated symbols.

20. The receiver unit of claim 19, wherein each correlator is further  
2 operative to despread the plurality of samples with a particular despread sequence to generate despread samples, and wherein the recovering is  
4 performed on the plurality of despread samples.

21. The receiver unit of claim 19,  
2 wherein each correlator is further operative to provide a first  
4 combination of recovered half-symbols for each Walsh symbol period of 2T in a  
first symbol stream and to provide a second combination of recovered half-  
symbols for each Walsh symbol period of 2T in a second symbol stream, and  
6 wherein the combiner is operative to combine the first symbol streams  
from the plurality of correlators to provide a first output symbol stream, and to  
8 combine the second symbol streams from the plurality of correlators to provide  
a second output symbol stream.

22. A method for processing a received signal in a wireless  
2 communications system, the method comprising:

4 generating a plurality of input samples from the received signal;  
6 recovering the plurality of input samples for a particular received signal  
instance to generate recovered half-symbols, wherein the recovering is  
8 performed with a channelization symbol having a length (T) that is half the  
length (2T) of a channelization symbol used to cover data symbols in the  
received signal;  
10 demodulating the recovered half-symbols with pilot estimates to  
generate correlated symbols; and  
12 selectively combining correlated symbols associated with one or more  
signal instances to provide demodulated symbols.

23. The method of claim 22, further comprising:

2 despreading the plurality of input samples with a despreading sequence  
4 associated with a signal instance being processed to generate a plurality of  
despread samples for the signal instance, and  
6 wherein the recovering is performed on the plurality of despread  
samples to generate the recovered half-symbols.

24. The method of claim 22, wherein the demodulating includes  
2 performing a dot product between the recovered half-symbols and the  
4 pilot estimates to provide dot symbols, and  
6 performing a cross product between the recovered half-symbols and the  
pilot estimates to provide cross symbols, and  
8 wherein the dot symbols and cross symbols for each channelization  
symbol period of 2T are selectively combined to provide the demodulated  
symbols.

25. A method for processing a received signal in a wireless  
2 communications system, wherein the received signal includes a first signal  
transmitted from a first antenna and a second signal transmitted from a second  
4 antenna, the method comprising:

6 generating a plurality of input samples from the received signal;  
8 processing at least one signal instance of each of the first and second  
signals to provide correlated symbols for each processed signal instance,  
10 wherein the processing for each signal instance includes  
despreading the plurality of input samples with a particular  
despreading sequence associated with the signal instance to provide a  
plurality of despread samples,  
12 recovering the plurality of despread samples to generate  
decovered half-symbols, wherein the recovering is performed with a  
14 Walsh symbol  $W$  having a length (T) that is half the length (2T) of a  
Walsh symbol  $W_{sts}$  used to cover data symbols in the received signal,  
16 and  
18 demodulating the recovered half-symbols with pilot estimates to  
generate the correlated symbols for the signal instance, wherein the pilot  
estimates are derived from the signal instance being processed; and  
20 selectively combining correlated symbols for the signal instances being  
processed to provide demodulated symbols.
